Abstract. Since the introduction of Lee's Inverse Projection (IP [7]), several modifications have been made to overcome some of its methodological limitations and make the procedure suitable for the existing sources, which may be very different from country to country.

The similar problems exist in demography in the form of projection and estimation of population age distributions and age-specific mortality rates. The problem of residual demography is estimation of demographic process in wild nature on its manifestation in marked subjects with unobserved age, which again is inverse problem.

Inverse projection is a logical inversion of conventional population projection techniques. The method is used to infer refined demographic statistics--mortality, fertility, and population age structures--from crude data--annual totals of births and deaths and an estimate of initial population size.

An inverse problem in science is the process of calculating from a set of observations the causal factors that produced them: for example, calculating an image in X-ray computed tomography, source reconstruction in acoustics, or calculating the density of the Earth from measurements of its gravity field.
