Iron oxides are chemical compounds composed of iron and oxygen. All together, there are sixteen known iron oxides and oxyhydroxides. Iron oxides and oxide-hydroxides are widespread in nature, play an important role in many geological and biological processes, and are widely used by humans, e.g., as iron ores, pigments, catalysts, in thermite (see the diagram) and hemoglobin.

### **Iron oxide - Wikipedia**

Iron(III) oxide or ferric oxide is the inorganic compound with the formula  $\text{Fe}_2\text{O}_3$ . It is one of the three main oxides of iron, the other two being iron(II) oxide ( $\text{FeO}$ ), which is rare, and iron(II,III) oxide ( $\text{Fe}_3\text{O}_4$ ), which also occurs naturally as the mineral magnetite. As the mineral known as hematite,  $\text{Fe}_2\text{O}_3$  is the main source of iron for the steel industry.

Iron oxide nanoparticles with mean diameter ranging from 7 to 20 nm were synthesized using two routes: the precipitation method in controlled atmosphere and a reduction-precipitation method under air, in some cases followed by a hydrothermal treatment. The smallest nanoparticles were obtained by the reduction-precipitation method.

The only likely source of the heat great enough to actually "melt" significant quantities of iron in the piles (or even just raise so much of it to red-hot or to 2000F) would be chemical energy (i.e., "combustion" of some sort).

SECTION 2. PROCESSING Ferrites are manufactured by processing a composition of iron oxide mixed with other major constituents such as oxides or carbonates of either manganese and zinc or nickel and zinc.
