Research efforts are underway to probe biological molecules with Raman spectroscopy in three states - crystal, semi-solid, and solution - to illuminate the structural transformations that occur across phases. The optical characterization of biological molecules using vibrational spectroscopy supplies detailed structural information.

Direct comparison demonstrated a correlation between calculated and experimentally observed spectra of the RNA polymers, thus confirming that the fundamental physical nature of the observed resonance structure is caused by the internal vibration modes in the macromolecules. In this work we demonstrate results from Fourier-Transform Infrared (FTIR) spectroscopy of DNA macromolecules and related biological materials in the terahertz frequency range.

The vibrational modes of biological molecules have been studied in many different biomolecules with different emphasis (Dexheimer 2007; Laman et al. 2008).

The terahertz frequency absorption spectra of DNA molecules reflect low-frequency internal helical vibrations involving rigidly bound subgroups that are connected by the weakest bonds, including the hydrogen bonds of the DNA base pairs, and/or non-bonded interactions.
