Today VLSI circuits with over 3 million transistors on a chip, with effective or electrical channel lengths of 0.5 microns, are in volume production. Designing such complex chips is virtually impossible without simulation tools which help to predict circuit behavior before actual circuits are fabricated.

For simulation purposes, we model a VLSI system as a collection of logic elements at varying levels of abstraction (e.g., transistors, NAND gates, flip flops, multipliers, etc.) and their interconnecting wires. Input vectors are then provided to exercise the circuit. A gate-level example using three logic elements is shown in Figure 1.
